

# Conditional simulations of max-stable processes

C. Dombry<sup>†</sup>,      F. Éyi-Minko<sup>†</sup>,      M. Ribatet<sup>‡</sup>

<sup>†</sup> Laboratoire de Mathématiques et Application, Université de Poitiers

<sup>‡</sup> Institut de Mathématiques et de Modélisation, Université Montpellier 2

**Definition 1.** A process  $Z$  defined on a compact metric space  $\mathcal{X}$  is **max-i.d.** in  $C(\mathcal{X})$  if it is sample continuous and for each  $n \in \mathbb{N}$ , there exists independent identically distributed sample continuous processes  $Z_{i,n}$  such that

$$Z \stackrel{d}{=} \max_{i=1,\dots,n} Z_{i,n}, \quad n \in \mathbb{N}, \quad (1)$$

where  $(\max Z_{i,n})(x) = \max Z_{i,n}(x)$  for all  $x \in \mathcal{X}$ .

*Remark.* If (1) holds with

$$Z_{i,n} = \frac{Z_i - b_n}{a_n},$$

for some continuous functions  $a_n > 0$  and  $b_n \in \mathbb{R}$  and where  $Z_i$  are independent copies of  $Z$ , then  $Z$  is said to be **max-stable**.

**Theorem 1** (de Haan 1984 & Giné, Hahn and Vatan 1990). *Let  $Z$  be a max-.i.d. process on  $\mathcal{X}$  such that  $\text{ess inf } Z(x) \equiv 0$ . Then there exists a unique  $\sigma$ -finite measure  $\Lambda$  on  $\mathcal{C}_0 = \mathcal{C}\{\mathcal{X}, [0, \infty)\} \setminus \{0\}$  such that*

$$Z \stackrel{d}{=} \max_{\varphi \in \Phi} \varphi,$$

where  $\Phi$  is a Poisson point process on  $\mathcal{C}_0$  with intensity measure  $\Lambda$ .

*Remark.* If  $Z$  is max-stable with unit Fréchet margins, i.e.,  $\Pr\{Z(x) \leq z\} = \exp(-1/z)$ ,  $z > 0$ , then

$$d\Lambda = \zeta^{-2} d\zeta d\sigma,$$

where  $\sigma$  is a **finite** measure on  $\mathcal{C}_1 = \{f \in \mathcal{C}_0 : \|f\| = 1\}$  such that

$$\int_{\mathcal{C}_1} f(x) d\sigma(f) = 1, \quad x \in \mathcal{X}.$$

- The specific form of the intensity measure  $d\Lambda = \zeta^{-2} d\xi d\sigma$  is well known in extreme value theory.
- It factorizes into a **radial** part  $\zeta^{-2}$  and an **angular** part  $\sigma$  using the bijection

$$\begin{aligned}\mathcal{C}_0 &\longrightarrow (0, \infty) \times \mathcal{C}_1 \\ f &\longmapsto (\underbrace{\|f\|}_{\text{radial}}, \underbrace{f/\|f\|}_{\text{angular}}).\end{aligned}$$

- The measure  $\sigma$  is called the **spectral measure** and characterizes the spatial dependence of extremes—**independently from the radius**.

👉 For statistical purposes, it is often more convenient to “think of”  $\sigma$  as the distribution of a non-negative, sample continuous stochastic process  $Y$  such that  $\mathbb{E}\{Y(x)\} = 1, x \in \mathcal{X}$ .

$$\varphi_i(x) = \zeta_i \phi(x - U_i; 0, \Sigma), \quad x \in \mathcal{X},$$

where  $\{(\zeta_i, U_i)\}_{i \geq 1}$  are the points of a Poisson process on  $(0, \infty) \times \mathbb{R}^d$  with intensity measure  $d\Lambda(\zeta, u) = \zeta^{-2} d\zeta du$  and  $\phi(\cdot; 0, \Sigma)$  is the centered  $d$ -variate normal density with covariance matrix  $\Sigma$ .

**Figure 1:** One realization from a Smith process on  $[-10, 10]$  with  $\Sigma = 3$ .

$$\varphi_i(x) = \sqrt{2\pi}\zeta_i \max\{0, \varepsilon_i(x)\}, \quad x \in \mathcal{X},$$

where  $\{\zeta_i\}_{i \geq 1}$  are the points of a Poisson process on  $(0, \infty)$  with intensity measure  $d\Lambda(\zeta) = \zeta^{-2} d\zeta$  and  $\varepsilon_i$  independent copies of a standard Gaussian process.

**Figure 2:** One realization from a Schlather process on  $[-10, 10]$  with correlation function  $\rho(h) = \exp(-h/3)$ .

$$\varphi_i(x) = \zeta_i \exp\{\varepsilon_i(x) - \gamma(x)\}, \quad x \in \mathcal{X},$$

where  $\{\zeta_i\}_{i \geq 1}$  are the points of a Poisson process on  $(0, \infty)$  with intensity measure  $d\Lambda(\zeta) = \zeta^{-2} d\zeta$  and  $\varepsilon_i$  independent copies of a centered Gaussian process with semi variogram  $\gamma$ .

**Figure 3:** One realization from a Brown–Resnick process on  $[-10, 10]$  with semi variogram  $\gamma(h) = \sqrt{h/3}$ .

Let  $\mathbf{x} \in \mathcal{X}^k$  and  $\mathbf{z} = (0, \infty)^k$ , then

$$\Pr\{Z(\mathbf{x}) \leq \mathbf{z}\} = \exp\left[-\Lambda\{(\mathbf{0}, \mathbf{z})^c\}\right] = \exp\{-V(\mathbf{z})\}.$$

Let  $\mathbf{x} \in \mathcal{X}^k$  and  $\mathbf{z} = (0, \infty)^k$ , then

$$\Pr\{Z(\mathbf{x}) \leq \mathbf{z}\} = \exp[-\Lambda\{(\mathbf{0}, \mathbf{z})^c\}] = \exp\{-V(\mathbf{z})\}.$$

In particular when

$$k = 2: \quad f(\mathbf{z}) = (V_1 V_2 - V_{12}) \exp\{-V(\mathbf{z})\}$$

$$k = 3: \quad f(\mathbf{z}) = (-V_1 V_2 V_3 + V_{12} V_3 + V_{13} V_2 + V_1 V_{23} - V_{123}) \exp\{-V(\mathbf{z})\}$$

$$k = n: \quad f(\mathbf{z}) = (\text{sum of many many terms}) \exp\{-V(\mathbf{z})\}$$

 Use of the maximum pairwise likelihood estimator

$$\hat{\theta}_p = \operatorname{argmax}_{\theta \in \Theta} \sum_{i=1}^{k-1} \sum_{j=i+1}^k \omega_{i,j} \ln f(z_i, z_j; \theta).$$

- Let  $Z$  be a max-stable process defined on  $\mathcal{X}$  with unit Fréchet margins.
- We observe  $Z$  at some conditioning locations  $\mathbf{x} = (x_1, \dots, x_k) \in \mathcal{X}^k$  giving rise to some (critical) values  $\mathbf{z} = (z_1, \dots, z_k) \in (0, \infty)^k$ .

- Let  $Z$  be a max-stable process defined on  $\mathcal{X}$  with unit Fréchet margins.
- We observe  $Z$  at some conditioning locations  $\mathbf{x} = (x_1, \dots, x_k) \in \mathcal{X}^k$  giving rise to some (critical) values  $\mathbf{z} = (z_1, \dots, z_k) \in (0, \infty)^k$ .

👉 Our goal is to sample from  $Z(\cdot) \mid \{Z(x_1) = z_1, \dots, Z(x_k) = z_k\}$ .

- The atoms of  $\Phi^+$  are only of interest if we restrict our attention to the conditioning points  $\mathbf{x}$ ;
- But most often one would like to get realizations at  $\mathbf{s} \neq \mathbf{x}$ .

👉 The atoms of  $\Phi^-$  are needed since it is likely that  $\max \Phi^-(\mathbf{s}) > \max \Phi^+(\mathbf{s})!$

$$Z(\mathbf{x}) = \max_{i \geq 1} \varphi_i(\mathbf{x}), \quad \mathbf{x} = (x_1, \dots, x_k).$$

- The Poisson point process  $\{\varphi_i(\mathbf{x})\}_{i \geq 1}$  has intensity measure

$$\Lambda_{\mathbf{x}}(A) = \int_0^\infty \Pr\{\zeta Y(\mathbf{x}) \in A\} \zeta^{-2} d\zeta, \quad \text{Borel set } A \subset \mathbb{R}^k.$$

- We assume that  $\Phi$  is **regular**, i.e.,  $\Lambda_{\mathbf{x}}(dz) = \lambda_{\mathbf{x}}(z) dz$ , for all  $\mathbf{x} \in \mathcal{X}^k$ .

$$Z(\mathbf{x}) = \max_{i \geq 1} \varphi_i(\mathbf{x}), \quad \mathbf{x} = (x_1, \dots, x_k).$$

- The Poisson point process  $\{\varphi_i(\mathbf{x})\}_{i \geq 1}$  has intensity measure

$$\Lambda_{\mathbf{x}}(A) = \int_0^\infty \Pr\{\zeta Y(\mathbf{x}) \in A\} \zeta^{-2} d\zeta, \quad \text{Borel set } A \subset \mathbb{R}^k.$$

- We assume that  $\Phi$  is **regular**, i.e.,  $\Lambda_{\mathbf{x}}(d\mathbf{z}) = \lambda_{\mathbf{x}}(\mathbf{z}) d\mathbf{z}$ , for all  $\mathbf{x} \in \mathcal{X}^k$ .

👉 Key point #2: The conditional intensity function

$$\lambda_{\mathbf{x}_1 | \mathbf{x}_2, \mathbf{z}_2}(\mathbf{u}) = \frac{\lambda_{(\mathbf{x}_1, \mathbf{x}_2)}(\mathbf{u}, \mathbf{z}_2)}{\lambda_{\mathbf{x}_2}(\mathbf{z}_2)}, \quad \mathbf{x} = (\mathbf{x}_1, \mathbf{x}_2), \mathbf{z} = (\mathbf{z}_1, \mathbf{z}_2),$$

characterizes (up to a truncation) the distribution of the extremal functions.

Here the set  $\{x_1, \dots, x_5\}$  is partitioned into  $(\{x_1, x_3\}, \{x_2\}, \{x_4\}, \{x_5\})$

- The hitting bounds  $\{z_i\}_{i=1, \dots, k}$  might be reached by several extremal functions, i.e.,  $\Phi^+ = \{\varphi_1^+, \dots, \varphi_k^+\} = \{\varphi_1^+, \dots, \varphi_\ell^+\}$  a.s.,  $1 \leq \ell \leq k$ .
- So we need to take into account all possible ways these hitting bounds are reached: **the hitting scenarios**

☞ These are the first 20 Bell numbers.

*Remark.* Recall that  $Bell(k)$  is the number of partitions of a set with  $k$  elements.

$$\# \text{ hitting scenarios} = \text{Card}(\mathcal{P}_k) = Bell(k)$$

1. Conditional distributions

2. MCMC sampler

▷ Computational burden

Full conditional distributions

If the full conditional distributions are nice,

...

... the state space

$\mathcal{P}_k$  isn't! (really?)

3. Simulation Study

4. Applications

- In Step 1, we need to sample from a discrete distribution whose **state space is  $\mathcal{P}_k$** , i.e., all possible hitting scenarios.

 **Combinatorial explosion** 

Hence we cannot compute  $C(\mathbf{x}, \mathbf{z})$  in

$$\pi_{\mathbf{x}}(\mathbf{z}, \tau) = \frac{1}{C(\mathbf{x}, \mathbf{z})} \prod_{j=1}^{|\tau|} \lambda_{\mathbf{x}_{\tau_j}}(\mathbf{z}_{\tau_j}) \int_{\{\mathbf{u} < \mathbf{z}_{\tau_j}^c\}} \lambda_{\mathbf{x}_{\tau_j}^c | \mathbf{x}_{\tau_j}, \mathbf{z}_{\tau_j}}(\mathbf{u}) d\mathbf{u}.$$

4. Applications

But how do I implement a Gibbs sampler whose states are partitions of a set???

**Lemma 1.** *There is a one-one mapping between  $\mathcal{P}_k$  and*

$$\mathcal{P}_k^* = \left\{ (a_1, \dots, a_k), \forall i \in \{2, \dots, k\}: a_1 \leq a_i \leq \max_{1 \leq j < i} a_j + 1, a_i \in \mathbb{Z} \right\},$$

*where  $a_1 = 1$  by convention.*

**Example 3.**  $(\{x_1, x_2\}, \{x_3\})$  is identified to  $(1, 1, 2)$  while  $(\{x_1, x_3\}, \{x_2\})$  is identified to  $(1, 2, 1)$ .

- We fit a Schlather process by maximizing the **pairwise likelihood** with the following trend surfaces

$$\eta(x) = \beta_{0,\eta} + \beta_{1,\eta} \text{alt}(x),$$

$$\sigma(x) = \beta_{0,\sigma},$$

$$\xi(x) = \beta_{0,\xi} + \beta_{1,\xi} \text{alt}(x),$$

where  $\eta(x)$ ,  $\sigma(x)$ ,  $\xi(x)$  are the location, scale and shape parameters of the generalized extreme value distribution and  $\text{alt}(x)$  the altitude of the stations at which the data are observed.

- We fit a Schlather process by maximizing the **pairwise likelihood** with the following trend surfaces

$$\eta(x) = \beta_{0,\eta} + \beta_{1,\eta} \text{alt}(x),$$

$$\sigma(x) = \beta_{0,\sigma},$$

$$\xi(x) = \beta_{0,\xi} + \beta_{1,\xi} \text{alt}(x),$$

where  $\eta(x)$ ,  $\sigma(x)$ ,  $\xi(x)$  are the location, scale and shape parameters of the generalized extreme value distribution and  $\text{alt}(x)$  the altitude of the stations at which the data are observed.

- **Take as conditional event the values observed during the 2003 European heatwave.**
- Simulate a Markov chain of length 10000 from  $\pi_{\mathbf{x}}(\mathbf{z}, \cdot)$  to estimate the distribution of the partition size.
- And perform a bunch of conditional simulations from our fitted model to get a nice map!

What's next?

**Table 5:** Empirical distribution of the partition size for the temperature data estimated from a simulated Markov chain of length 10000.

Partition size	1	2	3	4	5–16
Empirical probabilities (%)	2.47	21.55	64.63	10.74	0.61

- Around **90% of the time**, the conditional simulations are a consequence of **at most 3 extremal functions**;
- Inspecting the data, we found that the annual maxima in 2003 occurred between the 11th and 13rd of August

- What's next?

**Figure 14:** Left: Topographical map of Switzerland showing the sites and altitudes in metres above sea level of 16 weather stations for which annual maxima temperature data are available. Right: Map of temperature anomalies ( $^{\circ}\text{C}$ ), i.e., the difference between the point-wise medians obtained from 10000 conditional simulations and unconditional medians estimated from the fitted Schlather process.

- As expected the largest deviations occur in the plateau region of Switzerland
- The differences range between  $2.5^{\circ}\text{C}$  and  $4.75^{\circ}\text{C}$
